2 Data Structures

2.1 Segment Tree

To deal with queries on intervals, we use segment tree.

```
int arr[SIZE];
int tree[TREE_SIZE];
int makeTree(int left,int right,int node)
{
    if (left == right)
        return tree[node] = arr[left];
    int mid = (left + right) / 2;
    tree[node] += makeTree(left, mid, node * 2);
    tree[node] += makeTree(mid + 1,right, node * 2 +1);
    return tree[node];
}
```

Updating segment Tree

```
void update(int left,int right,int node, int change_node ,int diff)
{
    if (!(left <= change_node &&change_node <= right))
        return; //No effect on such nodes.
    tree[node] += diff; // This part must be changed with tree function.
    if (left != right)
    {
        int mid = (left + right) / 2;
        update(left, mid, node * 2, change_node, diff);
        update(mid +1,right, node * 2 +1, change_node, diff);
    }
}
```

Answering queries via segment tree

```
/*
Our Search range : start to end
Node has range left to right
We may answer query in O(log n) time.
*/
int Query(int node, int left, int right, int start, int end)
{
    if (right < start || end < left)
```

```
        return 0; //Node is out of range
    if (start <= left && right <= end)
        return tree[node]; //If node is completely in range
    int mid = (left + right) / 2;
    return Query(node * 2, left, mid, start, end)
        +Query(node*2+1,mid+1,right,start,end);
}
```
